Female full-time employment rate, 2000-2020

Methodology
and data sources

## Definitions and terminology

OECD: For the purposes of this report, this refers to the 33 OECD countries included in the PwC Women in Work Index. This consists of all OECD members except for Colombia, Costa Rica, Latvia, Lithuania and Turkey. The only exception to this is in Section 5 (Impact of the transition to net zero). When we refer to the OECD in this section, this refers to 28 of the 33 OECD countries on our Index. This is because this analysis uses scenario data on jobs composition at 2030 from the ILO and is not available for all countries. The 5 countries included in our Index but not in the net zero analysis include Canada, Chile, Iceland, Israel and New Zealand.

OECD average: This refers to the average taken across all 33 OECD countries in the Women in Work Index and applies where we discuss 2020 data relating to the main Index results and potential long-term economics gains. It does not adjust for the population size of different OECD countries.

Gender and sex: The Authors would like to acknowledge the limitation of the report in its focus on binary gender identities ('men' and 'women'), which excludes analysis of the employment outcomes and experiences of those who identify their gender differently, beyond these two
categories. This is mainly due to a lack of available data for other gender identities. Furthermore, in cases where data sources have been disaggregated by 'sex' rather than 'gender', the assumption has been applied that a person's gender identity is aligned with their biological sex characteristics (e.g. we have used 'female' and 'women' interchangeably in some places), however we recognise that the two are not equivalent and that this is not always the case.

Race and ethnicity: Throughout the report we frequently use the terms White and Ethnic Minority (as well as referring to other ethnic groups such as Black and Mixed Ethnic Group) and report on findings for White and Ethnic Minority people as a whole. We acknowledge the limitations of this approach and recognise that the employment outcomes and experiences of people who fall within these groups will vary significantly and that are many types of Ethnic Minority groups, including White Ethnic Minority groups. We also acknowledge that people may prefer to self-identify using other terms such as People of Colour.

## Changes to PwC's Women in Work Index results for 2019

Due to retrospective changes to the OECD and Eurostat gender pay gap data used in the Index, the Index scores and rankings for 2019 for have changed compared to those reported in the PwC Women in Work Index 2021 (last year's Index).

At the time of publication of the 2021 Index, actual data for the gender pay gap for 2019 was not available for the majority of countries in the Index. Therefore, we estimated the 2019 gender pay gap by linearly extrapolating historical data. At the time of publication of the Index this year, actual gender pay gap data for 2019 is now available for all OECD countries. We have revised and updated the 2019 estimated gender pay gap with actual data resulting in changes to the Index score and rank in 2019 for a number of countries in the Index.

Changes to the rankings of each country as a result of the update to the gender pay gap data can be seen in the adjacent table.

- Estonia's ranking changed the most, moving five places from 19th to 14th place. This was due to a decrease in the gender pay gap by 2 percentage points from $24 \%$ to $22 \%$ following the revision.
- Hungary's ranking also changed by 5 places, but unlike Estonia's, it's ranking was revised down, from 18th to 23 rd. This was due to the gender pay gap increasing by 5 percentage points from $13 \%$ to $18 \%$.
- Portugal's gender pay gap was revised down by 3 percentage points and the country's ranking showed the next largest Index movement, rising three places from 9th to 6th place
- The United States, Germany and Czechia all saw their ranking rise by two places whilst Australia and Switzerland's ranking saw a decline of two places following the revisions.
- The UK's ranking did not change and its gender pay gap remained at $16 \%$.

Changes to Index rankings for 2019

| Country | 2019 (old) | 2019 (updated) | Change in ranking |
| :---: | :---: | :---: | :---: |
| Australia | 15 | 17 | -2 |
| Austria | 25 | 25 | 0 |
| Belgium | 10 | 10 | 0 |
| Canada | 12 | 12 | 0 |
| Chile | 31 | 31 | 0 |
| Czechia | 22 | 20 | 2 |
| Denmark | 7 | 8 | -1 |
| Estonia | 19 | 14 | 5 |
| Finland | 8 | 9 | -1 |
| France | 23 | 24 | -1 |
| Germany | 21 | 19 | 2 |
| Greece | 30 | 30 | 0 |
| Hungary | 18 | 23 | -5 |
| Iceland | 1 | 1 | 0 |

| Switzerland | 13 | 15 | -2 |
| United Kingdom | 16 | 16 | 0 |
| United States | 24 | 22 | 2 |

## Index methodology Variables included in scoring

Our Index includes all OECD member countries except for Colombia, Costa Rica, Latvia, Lithuania and Turkey. The OECD average refers to the average taken across these 33 countries and applies where we discuss 2020 data relating to the main Index results and potential economics grains. Population size for different countries is not adjusted for.

| Variable | Weight \% | Factor | Rationale | Dataset(s) used |
| :---: | :---: | :---: | :---: | :---: |
| Gender pay gap | 25 | Constructed by subtracting median female income from median male income and expressing it relative to median male income. Wider pay gap penalised. | Higher share of full-time employment given higher score | Decile ratios of gross earnings, OECD <br> Series: Gender wage gap Frequency: Annual <br> Gender pay gap in unadjusted form by NACE Rev. 2 activity - structure of earnings survey methodology, Eurostat Frequency: Annual |
| Female labour force participation rate | 25 | Higher participation rates given higher score | Female economic participation is one of the cornerstones of economic empowerment, which is a factor of the level of skills and education of women, conducive workplace conditions and broader cultural attitudes outside the workplace (e.g. towards shared childcare and distribution of labour at home). | Labour force statistics by sex and age - indicators, OECD <br> Series: Labour force Frequency: Annual Age: 15 to 64 |
| Gap between female and male labour force participation rates | 20 | Higher female participation rate relative to male participation rate given higher score | Equality in participation rates reflect equal opportunities to seek and access employment opportunities in the workplace. | Labour force statistics by sex and age - indicators, OECD <br> Series: Labour force Frequency: Annual Age: 15 to 64 |
| Female unemployment rate | 20 | Higher unemployment penalised | The female unemployment rate reflects the economic vulnerability of women. Being unemployed can have longerterm impacts in the form of skills erosion, declining pension contributions and increased reliance on benefits. | Labour force statistics by sex and age - indicators, OECD <br> Series: Unemployment rate Frequency: Annual Age: 15 to 64 |
| Share of female employees in full-time employment | 10 | Higher share of fulltime employment given higher score | The tendency for part-time employment may adversely affect earnings, pensions and job security. However, this factor is given a lower weight in the Index since some women may prefer part-time jobs to fit flexibly with caring roles. <br> This variable only measures the share for women and does not compare with the share of male employees in full-time employment. | Incidence of FTPT <br> employment - common <br> definition, OECD <br> Series: Full-time employment <br> Frequency: Annual <br> Age: 15 to 64 <br> Household data, US Bureau of Labour Statistics <br> Series: Employed and unemployed full - and part-time workers by age, sex, race, and Hispanic or Latino ethnicity Frequency: Annual Age: 16 years and over |

## Data sources - UK regional data

We have applied the same methodology as for the main Index to construct the UK regional Index. This includes using the same weights and factors.

# Methodology for calculating potential GDP impacts from increasing employment rates 

We calculate a unit of full-time equivalent employment (FTE) as a unit of full-time employment plus half a unit of part-time employment. This is a measure of the effective labour force size, accounting for differences in output of part time and full time workers. We consider the potential boost to GDP under the following scenario:

- Increasing the female full-time equivalent employment rates (FTE) to that of a benchmark country (holding the male rates constant). We use Sweden as our benchmark country as it has the second highest female labour force participation rate. Iceland has the highest female labour force participation rate, however we use Sweden as it is a reasonably large economy and therefore a more suitable comparator country for the OECD.

## Simplifying assumptions

In order to estimate the GDP impacts of increasing female employment rates, with the data available, we have made the following simplifying assumptions:

- A full-time (FT) worker produces twice as much output on average as a part-time (PT) worker each year.
- Total employment in the economy is equal to employment within the 15-64 age group.

# Methodology for calculating potential gains to female earnings from closing the gender pay gap 

## We break down annual total earnings in the following way

## Simplifying assumptions

- In order to estimate the potential gains from closing the gender pay gap, we made the following simplifying assumption:
- Total employment in the economy is equal to employment within the 15-64 age group.
- The median wages are equivalent to the mean wages.
- The gender pay gap is closed by increasing female wages to match male wages.
- The elasticity of female employment to a change in wages is 0 , meaning that a $1 \%$ increase in wages results in no change in female employment. This takes into account the counteracting effects of labour supply and demand elasticities: an increase in wages makes it more expensive for employers to hire more workers, however higher earnings also incentivise potential workers to seek employment. Our literature review suggests that:
- Estimates of labour supply elasticity range from 0.5 to 0.962
- Estimates of labour demand elasticity range from 0.5 to - 0.363
- We take a conservative view that the counteracting effects cancel each other out with no resulting change in female employment.
- The simplifying assumptions provide us with conservative gain estimates because:
- The gender pay gap is likely to be higher at the mean, which may be skewed upwards by a small number of high earners amongst male employees, than at the median which has been used to obtain data for at least 10 countries, as noted in the data sources above.
- The 64+ age group has not been included in the analysis.

# Methodology for calculating the Index using forecasted data and estimating the impact of COVID-19 

To estimate the impact of COVID-19 and the future trajectory of the Women in Work Index, we used OECD country-level forecasts from December 2021 for (1) the unemployment rate (percentage) and (2) the labour force size (number of persons) in each Index country for 2021, 2022 and 2023. *We undertook the following steps:

1. We converted the OECD country-level forecasts for the two variables into year-on-year growth rates (2020-21, 2021-22, 2022-23). This provided an estimate of the annual growth rate of the unemployment rate and labour force size from 2020 through to 2023 for each country.

- This step was undertaken so that we had data that was suitable for input into our Index calculations. E.g. The OECD forecasts are for the labour force size whereas the Index requires the labour force participation rate as an input. We took the growth rate in the labour force size to be the same as the growth rate in the labour force participation rate - this is a reasonable assumption if the population size remains constant over the three years considered in the forecast.

2. We applied the growth rates for each variable to the 2020 Index variable values to generate estimates until 2023 for the following indicators:
i. Female unemployment rate
ii. Gap in male and female unemployment rate The male and female unemployment rates until 2023 were both generated separately before being differenced.
iii. Female labour force participation rate.

Since the OECD forecasts are not disaggregated by gender it was assumed that there is no difference in growth rates for men and women in both the unemployment rate and labour force forecasts.
3. Forecast data was not available to generate estimates for the remaining two Index indicators (female fulltime employment and gender pay gap) so these were held constant at 2020 values for our Index estimates 2021-23. As discussed in the main body of the report, this is likely to be a conservative approach as both indicators could have worsened as a result of the pandemic.

Key assumptions
\(\left.\begin{array}{l}Women and men see a proportionate <br>
change in the unemployment rate and the <br>

participation rate from COVID-19\end{array}\right\}\)| The gender pay gap and the female full |

| time employment rate are constant at |
| 2020 values until 2023 |

# Methodology for calculating the ethnicity pay gap 

## Our approach

Our data is sourced from the Annual Population Survey (APS). We first present simple comparisons of median hourly pay earned by individuals from different ethnic backgrounds and genders. While comparisons of median hourly earnings are useful, they alone do not take into account the differences between demographic characteristics that are common to different ethnic groups and genders. For example, on average men and women tend to work in different occupations, and ethnic groups are not evenly distributed across the country.

In order to account for this, we conduct a quantile regression analysis to estimate pay penalties. We define this as differences in pay when a selection of personal and work-related characteristics are held constant (see variables considered to the right). In other words, we try to compare 'like-for-like'.

When cleaning the data, we make a couple adjustments to account for data limitations. First, we remove the top $1 \%$ and bottom $2 \%$ of pay distribution from our data, in order to account for outliers. Second, we apply an income weight to the APS, to account for the poor response rate of earnings questions within the APS. This approach is consistent with that taken by the ONS. More information on the calculation of this weight can be found in Volume 6 of the Labour Force Survey User Guide.

## Personal and work related characteristics

 held constantFor our quantile regression, we use the logarithm of hourly pay as our dependent variable, controlling for the following independent variables:

- Logarithm of hourly pay
- Ethnicity
- Country of birth
- Sex
- Occupation
- Highest qualification obtained
- Age and age2
- Region
- Marital status
- Working pattern
- Sector of employment
- Gender * Ethnicity (interaction term)
- Gender * Working status (interaction term)
- Country of origin * Ethnicity (interaction term)

# Methodology for calculating the employment impacts of transition to net zero 

## Our approach

Our analysis uses a dataset developed by the International Labour Organisation (ILO). The ILO developed a multi-regional input-output model to estimate the employment impacts of the energy sector's transition to net zero. This model estimates the employment impacts not only within the energy sector but also the knock-on impacts of energy sector transitions on other sectors. The changes in the energy sector are in line with the transition to an 'energy sustainability' scenario that is associated with global warming of $2^{\circ} \mathrm{C}$. The dataset provides the employment composition across 163 exiobase sectors for 44 countries (disaggregated by gender and skill-level) at 2030, under the following two scenarios:
$2^{\circ} \mathrm{C}$ scenario: This scenario assumes that changes in energy production and consumption occur in line with the $2^{\circ} \mathrm{C}$ global warming scenario by the International Energy Agency (IEA).
$6^{\circ} \mathrm{C}$ scenario: This is a 'Business-As-Usual' scenario that assumes no climate action between now and 2030.

We filter the dataset to only include the OECD countries that are part of our Index. This gives us 28 out of the 33 countries included in the Index (excluding Canada, Chile, Iceland, Israel and New Zealand). We also split the dataset by male and female in order to get genderlevel results.

We then calculate the difference between the employment composition by sector and country in each of these two scenarios in order to quantify the employment impacts (job creation and job destruction). By calculating the difference between the two scenarios at 2030, we are able to control for any other drivers of change in employment between now and 2030, such as automation.Exiobase sectors are mapped to Standard Industry Classification sectors in order to get employment impacts results for our selected group of
countries by ISIC Rev. 4 sectors. Results for male and female workers are aggregated when assessing sectorlevel results. Results for male and female workers are compared in order to estimate the difference in net job gains for men and women.

This analysis only considers the energy sector's transition to net zero
The climate scenario we consider is based solely on the impact of transformations in energy production and consumption as the sector transitions to net zero. Examples of these transformations include the increased use of renewable energy sources and improved energy efficiency in buildings. The analysis does not account for the estimated employment impacts resulting from other transformations such as a transition to a circular economy mode (based on minimising resource use and extraction) or transformations within the agricultural sector. Therefore, our results do not capture the total magnitude of employment effects as a result of the transition to net zero.
